

GraphQL for Android

The code works, I don't know why

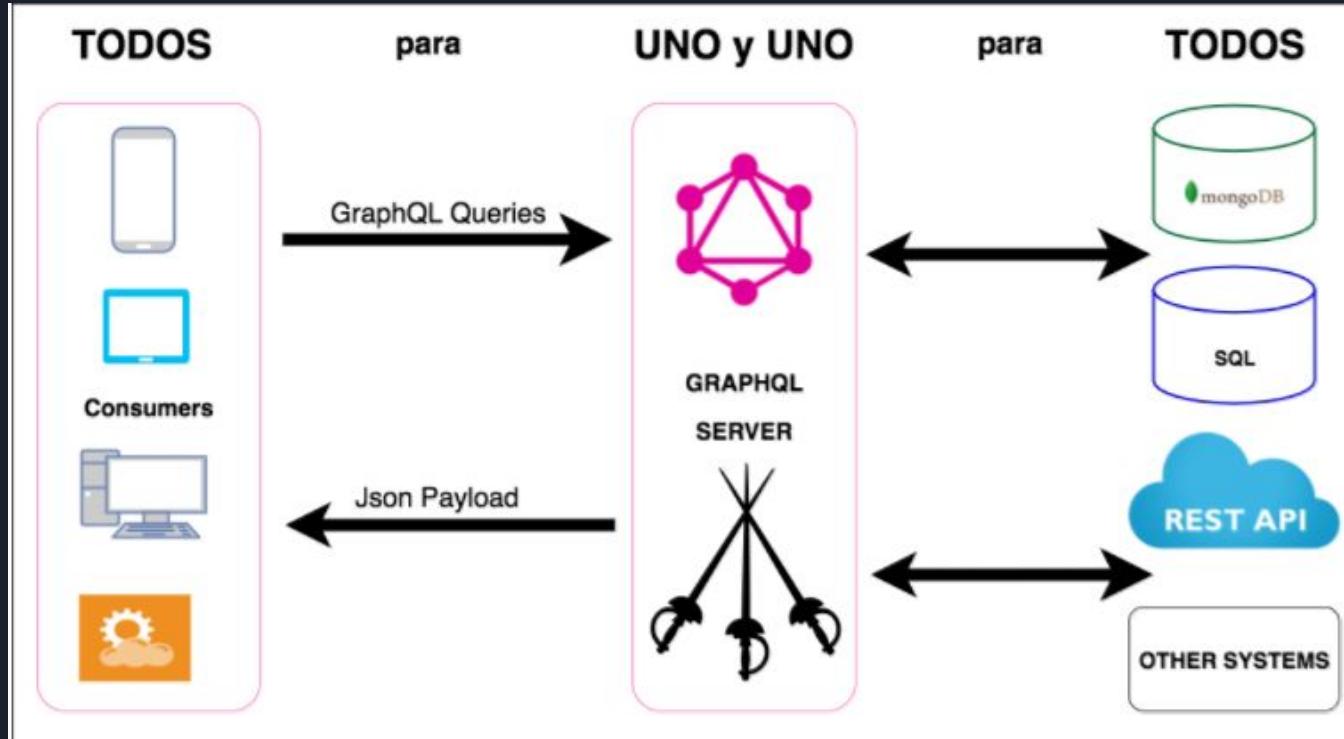

What is GraphQL

From the frontend point of view it is a query language for data APIs, and for the backend it is a runtime layer that needs to be implemented.

It is open source and was developed by Facebook, it is currently maintained by a large community of companies and individuals around the world.

How works?

and about Android?

Apollo Android is a GraphQL client that generates type-safe Kotlin models from your GraphQL queries. It also handles parsing and caching so you can focus on what matters most to your users and build beautiful mobile apps.

What I need?

- Android Studio Plugin
- Gradle Dependencies
- Server URL
- Define packageName
- We need the path main/graphql
- The Scheme *.dsl
- The query files

:Thanks!

It's not a bug, it's a feature
